

# EN3150 Assignment 03: Simple convolutional neural network to perform classification.

Sampath K. Perera

September 25, 2023

## 1 CNN for image classification

In this assignment, you will create a simple image classifier using convolutional neural network (CNN). You have the freedom to use any programming language and toolkit of your choice, but it is recommended to use the **Python** programming language along with **TensorFlow** and **Keras** or **PyTorch** to construct the convolutional neural network (CNN).

1. Why CNNs preferable for image classification over multilayered perceptrons (MLPs) or simple feedforward neural networks (NNs)?
2. Set up your environment: Ensure that you have installed all the required software packages.
3. Prepare your dataset: Download the CIFAR-10 dataset. This dataset contains 60,000 color images in 10 different classes. Documentation of this data set can be found in **CIFAR-10 dataset**. You may use listing 1 to load data. Further, apply suitable feature scaling. Refer this for more information "**pytorch normalization**".
4. Split the dataset into training, validation, and testing subsets using a ratio of 60% for training and 20% each for validation and testing sets<sup>1</sup>.

---

```
# for pytorch
import torchvision
import torchvision.transforms as transforms

# Define data transformations (optional, but
# recommended)
transform = transforms.Compose([transforms.ToTensor(),
                                transforms.Normalize((0.5, 0.5, 0.5), (0.5, 0.5,
                                0.5))])

# Load the training dataset
```

---

<sup>1</sup>If data set is too large to process, you may use portion of it.

```

train_dataset = torchvision.datasets.CIFAR10(root='./
data', train=True, transform=transform, download=
True)

# Load the testing dataset
test_dataset = torchvision.datasets.CIFAR10(root='./
data', train=False, transform=transform, download=
True)

# for keras

from keras.datasets import cifar10

# Load the CIFAR-10 dataset
(train_images, train_labels), (test_images,
test_labels) = cifar10.load_data()

```

Listing 1: Data loading.

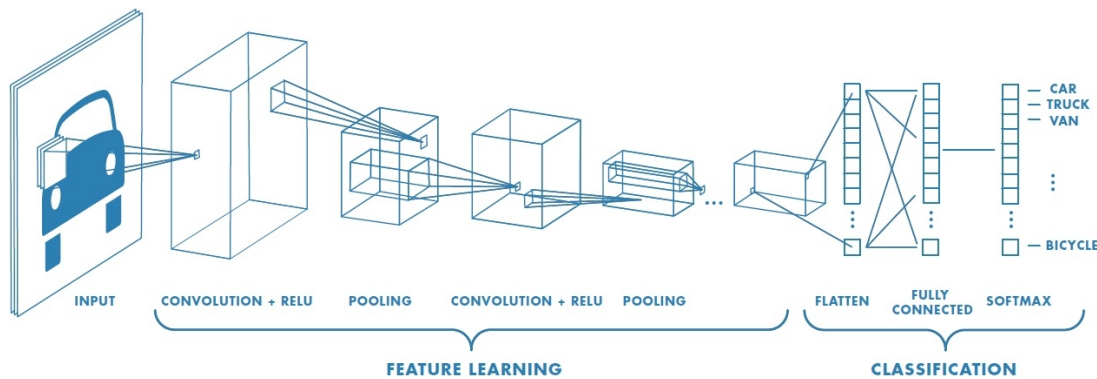

Figure 1: A simple CNN for image classification.

5. Build the CNN model: A common CNN design consists of interleaving convolutional and max-pooling layers, ending with a linear classification layer [1]. This pattern is illustrated in Figure 1<sup>2</sup>, and it was inspired by Fukushima’s neocognitron [2] and Hubel and Wiesel’s work on human visual cortex [3]. Yann LeCun’s LeNet model refined this approach in 1998, popularizing it through backpropagation and SGD [4]. In this example (Figure 1), we exclude normalization layers from the CNN design because the model is relatively simple and not very deep. Here, the benefits of normalization layers may not be visible. However, in deep neural networks, normalization layers, such as batch normalization or layer normalization, are often used to improve training stability. They help mitigate issues like vanishing gradients and can make it easier for deep networks to converge during training. Refer [tensorflow batch normalization](#) and [pytorch batch normalization](#) for more information.

<sup>2</sup>Image adapted from <https://blog.floydhub.com>

A basic CNN architecture is given below. Feel free to modify this network by adding more layers.

- A Convolutional layer with  $x_1$  filters, a  $m_1 \times m_1$  kernel, and 'relu' activation.
  - A MaxPooling layer.
  - Another Convolutional layer with  $x_2$  filters, a  $m_2 \times m_2$  kernel, and 'relu' activation.
  - Another MaxPooling layer.
  - Flatten the output.
  - A fully connected layer with  $x_3$  units and 'relu' activation.
  - Add dropout with a rate of  $d$  to reduce overfitting.
  - An output layer with 10 units (for 10 classes) and 'softmax' activation.
6. Determine the parameters of the above network such as kernel sizes, filter sizes, size of the fully connected layer and dropout rate.
  7. Train the model: Train the model using the training data for 20 epochs and plot training and validation loss for with respect to epoch. Here, for the optimizer you may use adam and sparse categorical crossentropy as the loss function. Set a suitable learning rate. Refer this page to see available optimizers [keras optimizers](#) and [pytorch optimizers](#). More information about optimizer can be found in <https://cs231n.github.io/neural-networks>.
  8. Why we have chosen adam optimizer over SGD?
  9. Why we have chosen sparse categorical crossentropy as the loss function?
  10. Evaluate the Model: After training, evaluate the model's performance on the testing dataset. Record the train/test accuracy, confusion matrix, precision and recall.
  11. Plot training and validation loss for with respect to epoch for different learning rates such as 0.0001, 0.001, 0.01, and 0.1.

## 2 Compare your network with state-of-the-art networks

"In practice, training an entire convolutional network from scratch (starting with random initialization) is a rare occurrence. This is primarily due to the scarcity of datasets of sufficient size. Instead, a common approach is to first pretrain a CNN on an extensive dataset, such as ImageNet, which comprises 1.2 million images across 1000 categories. Subsequently, this pretrained CNN can be utilized as either an initialization point or a fixed feature extractor when tackling a specific task of interest. This is known as transfer learning"<sup>3</sup>.

---

<sup>3</sup><https://cs231n.github.io/transfer-learning/>

12. Choose two state-of-the-art pre-trained model or architecture like [ImageNet](#), [ResNet](#), [GoogLeNet](#), [AlexNet](#), [DenseNet](#) and [VGG](#).
13. Load the pre-trained model and fine-tune it for the CIFAR-10 dataset.
14. Train the fine-tuned model using the same training and testing data splits as your custom CNN model.
15. Record training and validation loss values for each epoch.
16. Evaluate the fine-tuned model on the testing dataset and calculate the test accuracy.
17. Compare the test accuracy of your custom CNN model with that of the fine-tuned state-of-the-art model.
18. Discuss trade-offs, advantages, and limitations of using a custom model versus a pre-trained model.

## 4 GitHub Profile

- You **must** include the link to your GitHub (or some other SVN) profile, so that I can see that you have worked on this assignment over a reasonable duration. Therefore, make commits regularly. However, I will use only the pdf for grading to save time.

## 5 Submission

- Upload a report and your codes as a zip file named as "EN3150\_your\_groupno\_A03.zip". Include the index numbers and the names of the group members within the report. Only one submission is required from a group.
- The interpretation of results and the discussion are important in the report.
- An extra penalty of 10% is applied for late submission.
- Plagiarism will be checked and in cases of plagiarism, an extra penalty of 10% will be applied.
